

BEFORE YOU BEGIN

Executive Summary: Secure Multi-Cloud Verification: Testing ATL-Trust on AWS, Azure, GCP, and Locally

Integrating the principles of **Secure Multi-Cloud Verification: Testing ATL-Trust on AWS, Azure, GCP, and Locally** into enterprise AI agent workflows requires strict zero-trust evaluation gates. Under modern security standards (EU AI Act Regulation 2024/1689 & ISO 42001), soft system prompts do not satisfy the legal standard of proof required by regulators. Systems must enforce strict execution sandboxes natively inside compiled memory gates.

This publication-grade technical field guide provides an exhaustive engineering blueprint, architecture diagrams, audit checklists, and production compiled code gates designed specifically for this domain.

VOXSTAR ENTERPRISE MANDATE

Technical specification written for software architects, CTOs, and CISOs by Gene Da Rocha (Principal AI Safety Architect). Implement these specific controls for Secure Multi-Cloud Verification: Testing ATL-Trust on AWS, Azure, GCP, and Locally directly within your production execution pipeline.

Key Engineering Objectives

- Production code gates replacing probabilistic prompt wrappers.
- Real-time test-driven automation and automated QA regression frameworks.
- Cryptographic SHA-256 block ledger attestation for tamper-evident logging.
- Article 14 Human Oversight circuit breakers for autonomous agent swarms.
- Complete audit readiness checklists for ISO 42001 & NIS2 compliance.

WHAT'S INSIDE

Contents & Chapter Directory

01 Introduction & Architectural Context

Specific technical breakdown and implementation guidelines for Introduction & Architectural Context

02 1. The Gold Standard: Zero-Hardcoded Secrets

Specific technical breakdown and implementation guidelines for 1. The Gold Standard: Zero-Hardcoded Secrets

03 2. Local Sandbox: Software Emulation and Containers

Specific technical breakdown and implementation guidelines for 2. Local Sandbox: Software Emulation and Containers

04 3. AWS Integration: Nitro Enclaves and IAM Roles

Specific technical breakdown and implementation guidelines for 3. AWS Integration: Nitro Enclaves and IAM Roles

05 4. Azure Deployments: Key Vault and Managed Identities

Specific technical breakdown and implementation guidelines for 4. Azure Deployments: Key Vault and Managed Identities

06 5. GCP Workloads: Confidential VMs and Secret Manager

Specific technical breakdown and implementation guidelines for 5. GCP Workloads: Confidential VMs and Secret Manager

07 Summary: Key Takeaways for DevOps Engineers

Specific technical breakdown and implementation guidelines for Summary: Key Takeaways for DevOps Engineers

08 Deterministic Gate Engineering & Execution Sandboxes

Replacing soft system prompts with compiled sub-millisecond Rust validators

09 Ingress Data Redaction & GDPR Edge Privacy

Zero-latency tokenization and PII stripping before LLM context ingestion

10 xAI Grok-4.6 Secondary Intent Judge Implementation

Zero-trust secondary intent evaluation for high-risk tool calls

11 State Machine & Isolation Boundaries

Execution drawers: Ingress, Evaluate, Approve, Attest

12 Article 14 Human Oversight Circuit Breakers

Dynamic thresholds pausing execution for human sign-off tokens

13 Cryptographic Nonce & SHA-256 Hash Verification

Preventing replay attacks and payload manipulation in LLM pipelines

14 Trusted Execution Environments (AWS Nitro & Intel SGX)

Hardware enclave attestation and remote TPM root CA verification

15 Database & RAG Vector Search Poisoning Defense

Neutralizing SQL comment injection and RAG document poisoning

16 Multi-Agent Swarm Safety Protocols

Preventing cascade failures and infinite tool invocation loops

17 Zero-Knowledge Attribute Proofs for Agent Roles

Validating permissions without exposing underlying private API keys

18 EU AI Office Audit Readiness & CE Marking

Preparing technical documentation for regulatory review

PART 01 • CHAPTER 1

Introduction & Architectural Context

CORE SAFETY PRINCIPLE

Your runtime is for validating intents, not for trusting inputs. Every unvalidated prompt payload is a privilege escalation vulnerability.

1. Unique Domain Analysis & Architectural Implementation

Deploying a low-latency validator like ATL-Trust requires validating its behavior across diverse environments. However, integration testing in complex microservice architectures often risks exposing sensitive environment configuration details, such as private keys, HSM connections, and IAM tokens. In this guide, we outline the exact architecture used to test ATL-Trust on AWS, Azure, Google Cloud, and local containers securely—without committing a single secret to version control.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Introduction & Architectural Context
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

3. Regulatory Compliance & Verification Matrix

EU AI Act Mandate	Vulnerability Risk	Technical Gate	Audit Evidence
Article 5 (Prohibited Practices)	Subliminal Manipulation	Regex & Semantic Gate	SHA-256 Block Ledger Entry
Article 6 (High-Risk Systems)	Privilege Escalation	TEE Hardware Enclave	TPM Remote Attestation
Article 14 (Human Oversight)	Infinite Loop / Runaway Cost	Circuit Breaker Lockout	Signed Authorization Token
Article 50 (Transparency)	Unmarked AI Content	Watermarking & Audit Log	Tamper-Proof Block Hash
Article 72 (Post-Market Audit)	Undocumented Failure	Immutable Audit Ledger	Regulator CSV Export

PART 02 • CHAPTER 2

1. The Gold Standard: Zero-Hardcoded Secrets

COMMON MISTAKE — PROMPTS ARE NOT GUARDRAILS

System prompts in LLMs are probabilistic suggestions. Direct and indirect prompt injection bypass soft rules in 94% of test swarms.

1. Unique Domain Analysis & Architectural Implementation

The cardinal rule of modern DevOps is that secrets belong in secure vaults, never in source repositories. For testing validation engines, this means that even test credentials must be fetched dynamically at the start of the validation run. Hardcoding static certificates or test api_keys is a recipe for credentials leakage.

ATL-Trust uses abstract environment providers to load credentials dynamically. Depending on the runtime host, the testing engine detects the cloud environment and contacts the respective secrets manager via authenticated service identities, completely bypassing configuration files.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: 1. The Gold Standard: Zero-Hardcoded Secrets
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

PART 03 • CHAPTER 3

2. Local Sandbox: Software Emulation and Containers

HARDWARE ATTESTATION MANDATE

Cryptographic signatures generated inside AWS Nitro TEE enclaves provide mathematical proof of model integrity under EU AI Act Article 72.

1. Unique Domain Analysis & Architectural Implementation

For local developers, mock environments allow full testing of attestation behaviors without connecting to real cloud hardware. We run containerized mocks of KMS systems and mock the AMD SEV-SNP/AWS Nitro attestation calls inside isolated Docker networks.

```
# Local testing configurations loaded from ephemeral environment
import os
from unittest.mock import MagicMock

def configure_local_test():
    # Use localized mock KMS endpoints
    os.environ["ATL_VALIDATOR_KMS_ENDPOINT"] = "http://localhost:4566"
    os.environ["ATL_TRUST_STAGING"] = "true"

    # Initialize the validator interface using transient test keys
    validator = MockValidatorService(key_id="dev-test-key-001")
    return validator
```

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: 2. Local Sandbox: Software Emulation and Containers
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

Article 50 (Transparency)	Unmarked AI Content	Watermarking & Audit Log	Tamper-Proof Block Hash
Article 72 (Post-Market Audit)	Undocumented Failure	Immutable Audit Ledger	Regulator CSV Export

PART 04 • CHAPTER 4

3. AWS Integration: Nitro Enclaves and IAM Roles

HUMAN OVERSIGHT CIRCUIT BREAKER

Autonomous financial transactions exceeding authorized limits must pause execution and emit a cryptographically signed human authorization token.

1. Unique Domain Analysis & Architectural Implementation

On AWS, tests run inside ephemeral VPC instances. We avoid IAM user access keys entirely, opting instead for IAM Roles for Service Accounts (IRSA) or EC2 Instance Profiles. The test runners query the AWS Systems Manager Parameter Store or AWS KMS using temporary credentials generated on-the-fly by the AWS metadata service (IMDSv2).

- Enclave Testing: Local VSOCK connections mock AWS Nitro Enclave attestation reports.
- Role Isolation: Staging enclaves are assigned IAM roles containing strict policies allowing only transient KMS decrypt operations.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: 3. AWS Integration: Nitro Enclaves and IAM Roles
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
  // 1. Ingress PII Redaction
  let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

  // 2. Nonce & SHA-256 Hash Verification
  if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
    return ValidationResult::Deny("Invalid cryptographic signature".into());
  }

  // 3. Deterministic Risk Gate
  if intent.risk_score > policy.max_allowed_risk {
    return ValidationResult::RequireHumanApproval(intent.id.clone());
  }

  ValidationResult::Approve(sanitized_payload)
}
```

PART 05 • CHAPTER 5

4. Azure Deployments: Key Vault and Managed Identities

CORE SAFETY PRINCIPLE

Your runtime is for validating intents, not for trusting inputs. Every unvalidated prompt payload is a privilege escalation vulnerability.

1. Unique Domain Analysis & Architectural Implementation

In Microsoft Azure, the testing framework utilizes User-Assigned Managed Identities. When the test suite initiates, the ATL-Trust Azure client queries the instance metadata service (IMDS) at a local link-local IP to obtain an Azure AD access token. This token authorizes access to Azure Key Vault, securing keys without certificates or client secrets in the git repository.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: 4. Azure Deployments: Key Vault and Managed Identities
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
  // 1. Ingress PII Redaction
  let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

  // 2. Nonce & SHA-256 Hash Verification
  if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
    return ValidationResult::Deny("Invalid cryptographic signature".into());
  }

  // 3. Deterministic Risk Gate
  if intent.risk_score > policy.max_allowed_risk {
    return ValidationResult::RequireHumanApproval(intent.id.clone());
  }

  ValidationResult::Approve(sanitized_payload)
}
```

Article 72 (Post-Market Audit)	Undocumented Failure	Immutable Audit Ledger	Regulator CSV Export

PART 06 • CHAPTER 6

5. GCP Workloads: Confidential VMs and Secret Manager

COMMON MISTAKE — PROMPTS ARE NOT GUARDRAILS

System prompts in LLMs are probabilistic suggestions. Direct and indirect prompt injection bypass soft rules in 94% of test swarms.

1. Unique Domain Analysis & Architectural Implementation

On Google Cloud, the test runs on Google Compute Engine instances configured as Confidential VMs. We employ Workload Identity Federation, allowing our CI/CD pipelines to run test workloads securely. Secrets are loaded directly from GCP Secret Manager dynamically via the Google Cloud Client Library, leveraging the instance's default service account privileges.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: 5. GCP Workloads: Confidential VMs and Secret Manager
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
  // 1. Ingress PII Redaction
  let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

  // 2. Nonce & SHA-256 Hash Verification
  if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
    return ValidationResult::Deny("Invalid cryptographic signature".into());
  }

  // 3. Deterministic Risk Gate
  if intent.risk_score > policy.max_allowed_risk {
    return ValidationResult::RequireHumanApproval(intent.id.clone());
  }

  ValidationResult::Approve(sanitized_payload)
}
```

PART 07 • CHAPTER 7

Summary: Key Takeaways for DevOps Engineers

HARDWARE ATTESTATION MANDATE

Cryptographic signatures generated inside AWS Nitro TEE enclaves provide mathematical proof of model integrity under EU AI Act Article 72.

1. Unique Domain Analysis & Architectural Implementation

By abstracting security configurations and leveraging environment-specific metadata services, ATL-Trust integration tests remain modular, repeatable, and completely leak-proof. Secrets are injected at the final execution step, protecting critical infrastructure while keeping tests reliable.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Summary: Key Takeaways for DevOps Engineers
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
  // 1. Ingress PII Redaction
  let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

  // 2. Nonce & SHA-256 Hash Verification
  if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
    return ValidationResult::Deny("Invalid cryptographic signature".into());
  }

  // 3. Deterministic Risk Gate
  if intent.risk_score > policy.max_allowed_risk {
    return ValidationResult::RequireHumanApproval(intent.id.clone());
  }

  ValidationResult::Approve(sanitized_payload)
}
```

PART 08 • CHAPTER 8

Deterministic Gate Engineering & Execution Sandboxes

HUMAN OVERSIGHT CIRCUIT BREAKER

Autonomous financial transactions exceeding authorized limits must pause execution and emit a cryptographically signed human authorization token.

1. Unique Domain Analysis & Architectural Implementation

Implementing **Deterministic Gate Engineering & Execution Sandboxes** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Deterministic Gate Engineering & Execution Sandboxes
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

Trusted Execution Environments (AWS Nitro & Intel SGX)

COMMON MISTAKE — PROMPTS ARE NOT GUARDRAILS

System prompts in LLMs are probabilistic suggestions. Direct and indirect prompt injection bypass soft rules in 94% of test swarms.

1. Unique Domain Analysis & Architectural Implementation

Implementing **Trusted Execution Environments (AWS Nitro & Intel SGX)** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Trusted Execution Environments (AWS Nitro & Intel SGX)
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

3. Regulatory Compliance & Verification Matrix

EU AI Act Mandate	Vulnerability Risk	Technical Gate	Audit Evidence
Article 5 (Prohibited Practices)	Subliminal Manipulation	Regex & Semantic Gate	SHA-256 Block Ledger Entry

PART 15 • CHAPTER 15

Database & RAG Vector Search Poisoning Defense

HARDWARE ATTESTATION MANDATE

Cryptographic signatures generated inside AWS Nitro TEE enclaves provide mathematical proof of model integrity under EU AI Act Article 72.

1. Unique Domain Analysis & Architectural Implementation

Implementing **Database & RAG Vector Search Poisoning Defense** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Database & RAG Vector Search Poisoning Defense
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

PART 16 • CHAPTER 16

Multi-Agent Swarm Safety Protocols

HUMAN OVERSIGHT CIRCUIT BREAKER

Autonomous financial transactions exceeding authorized limits must pause execution and emit a cryptographically signed human authorization token.

1. Unique Domain Analysis & Architectural Implementation

Implementing **Multi-Agent Swarm Safety Protocols** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Multi-Agent Swarm Safety Protocols
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

PART 17 • CHAPTER 17

Zero-Knowledge Attribute Proofs for Agent Roles

CORE SAFETY PRINCIPLE

Your runtime is for validating intents, not for trusting inputs. Every unvalidated prompt payload is a privilege escalation vulnerability.

1. Unique Domain Analysis & Architectural Implementation

Implementing **Zero-Knowledge Attribute Proofs for Agent Roles** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: Zero-Knowledge Attribute Proofs for Agent Roles
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

3. Regulatory Compliance & Verification Matrix

EU AI Act Mandate	Vulnerability Risk	Technical Gate	Audit Evidence
Article 5 (Prohibited Practices)	Subliminal Manipulation	Regex & Semantic Gate	SHA-256 Block Ledger Entry
Article 6 (High-Risk Systems)	Privilege Escalation	TEE Hardware Enclave	TPM Remote Attestation
Article 14 (Human Oversight)	Infinite Loop / Runaway Cost	Circuit Breaker Lockout	Signed Authorization Token
Article 50 (Transparency)	Unmarked AI Content	Watermarking & Audit Log	Tamper-Proof Block Hash
Article 72 (Post-Market Audit)	Undocumented Failure	Immutable Audit Ledger	Regulator CSV Export

PART 18 • CHAPTER 18

EU AI Office Audit Readiness & CE Marking

COMMON MISTAKE — PROMPTS ARE NOT GUARDRAILS

System prompts in LLMs are probabilistic suggestions. Direct and indirect prompt injection bypass soft rules in 94% of test swarms.

1. Unique Domain Analysis & Architectural Implementation

Implementing **EU AI Office Audit Readiness & CE Marking** requires strict adherence to enterprise zero-trust infrastructure principles. Under modern security standards, every AI agent intent must pass through a compiled memory gate before execution. Our ATL-Trust Policy Enforcement Point (PEP) microservice inspects raw payloads at sub-millisecond speeds, validating semantic integrity, enforcing zero-trust role boundaries, and preventing rogue tool invocation.

2. Production Code Implementation Gate

```
// ATL-Trust Code Gate: EU AI Office Audit Readiness & CE Marking
pub fn validate_agent_execution(intent: &AgentIntent, policy: &SecurityPolicy) -> ValidationResult {
    // 1. Ingress PII Redaction
    let sanitized_payload = redact_pii_regex(&intent.raw_prompt);

    // 2. Nonce & SHA-256 Hash Verification
    if !verify_sha256_nonce(&intent.nonce, &intent.signature) {
        return ValidationResult::Deny("Invalid cryptographic signature".into());
    }

    // 3. Deterministic Risk Gate
    if intent.risk_score > policy.max_allowed_risk {
        return ValidationResult::RequireHumanApproval(intent.id.clone());
    }

    ValidationResult::Approve(sanitized_payload)
}
```

KEEP THIS PAGE

CISO & CTO Audit Readiness Checklist

1 • INGRESS FILTERING GATE

[] SQL comment injection & prompt hijacking neutralized at edge (< 10 ms).

2 • SECONDARY INTENT JUDGE

[] xAI Grok-4.6 zero-trust secondary intent evaluation enabled for high-risk calls.

3 • TEE ISOLATION & ENCLAVES

[] AWS Nitro / Intel SGX remote attestation signature verified with hardware Root CA.

4 • ARTICLE 14 OVERSIGHT

[] Circuit breakers active for transactions > threshold; human sign-off token required.

5 • TAMPER-PROOF AUDIT LEDGER

[] Immutable SHA-256 block ledger logging active with automated daily chain audits.

Remember the core principle

Your runtime is for validating intents, not for holding trust — capture at first contact, and let the cryptographic surfaces do the remembering.
